

Project Brief: Mock Authentication System

1. Project Overview

The goal of this task is to build a functional User Authentication flow (Registration, Login, and Profile) using React. Since we are not using a backend, you will use the “**Do your research to find where we need to store such data for now lets call it ‘MY-STORAGE’**” to act as your database and session manager.

2. Core Technical Requirements

To complete this task, your code must demonstrate:

- **Component Reusability:** Creating generic components (Inputs, Buttons, Cards) that are used across multiple pages.
 - **State Management:** Handling form data and authentication status using React `useState`.
 - **Persistence:** Saving and retrieving user data and "auth tokens" from ‘MY-STORAGE’.
 - **Navigation:** implement Navigation to move between pages.
-

3. Functional Requirements

A. Registration Page

- Create a form with fields: **Full Name, Email, and Password**.
- **Action:** When the user clicks "Register," save their data as an object in ‘MY-STORAGE’ (e.g., key: `user_data`).
- **Success:** Upon registration, redirect the user to the Login page.

B. Login Page

- Create a form with fields: **Email and Password**.
- **Action:** When "Login" is clicked, check if the entered email and password match the data stored in ‘MY-STORAGE’.
- **Token Handling:** If the credentials match, generate a random string (a "mock token") and save it in ‘MY-STORAGE’ (e.g., key: `auth_token`).
- **Redirect:** Send the user to the Profile page.

C. User Profile Page (Protected)

- **Auth Check:** This page should only be visible if an `auth_token` exists in `'MY-STORAGE'`. If it doesn't, redirect the user back to Login.
 - **The Profile Card:** Use a reusable `<Card />` component to display the user's information (Name and Email) retrieved from storage.
 - **Logout:** Add a "Logout" button that clears the `auth_token` from `'MY-STORAGE'` and redirects to the Login page.
-

4. Reusability Constraints (The "Do Not Repeat Yourself" Rule)

You are **required** to create the following reusable components and use them on every page:

1. `<Input />`: Should accept props for `label`, `type`, `placeholder`, and `value`.
2. `<Button />`: Should accept props for `text`, `onClick`, and `variant` (e.g., primary vs. secondary colors).
3. `<Card />`: A wrapper component used to display the User Profile information.
